In this tab we have to kind of information:

## Propagation data

First, data linked to the propagation with:

- Duration or date criteria for the end of the propagation
- Value of the duration or the date of the end of the propagation
- Altitude of the end of the propagation
- Type of altitude (since V11.4)

**Propagation conditions**

End propagation	<input checked="" type="radio"/> Duration	<input type="radio"/> Date
Duration	86400.0 <a href="#">s</a>	
Stop altitude	100.0 <a href="#">km</a>	
Altitude type	<input checked="" type="radio"/> Geodetic	<input type="radio"/> Geocentric
Propagation frame	GCRF	<a href="#">▼</a>

*Note: the propagation will stop once the first event (date or altitude) will occur.*

*Note: it is possible to retro propagate a trajectory by giving a negative duration or a date previous to the initial one.*

- Frame used for the propagation (only inertial ones among **CIRF**, **EME2000** and **GCRF**); the first one is recommended in term of **CPU** time.

## Numerical integrator

Then, we will have numerical integrator tuning:

- If the user chooses a **Runge Kutta**, only the step will have to be entered
- If the **Dormand Price** is selected the user will have to tune min/max steps and tolerances (but by default values are available).

Note: since V11.4 and due to the V4.4 version of [PATRIUS](#) a specific option is available to by-pass the error mode when minimum step is reached. In that case, the precision given by tolerances will not be reached but the propagation will go on.

Note: since V11.4 some typical tuning is proposed depending on the kind of orbit and the desired precision.
